Summary

This paper describes a field study jointly conducted by Myanmar and Japan in February 2019 to document the plant genetic resources (PGRs) of Chin State, Myanmar. The study was a part of PGRAsia, an international joint research project between the Japanese research institutes and gene banks of Asian countries, consigned by the Ministry of Agriculture, Forestry and Fisheries to the National Agriculture and Food Research Organization (NARO) of Japan. It was implemented under a Memorandum of Understanding between NARO and the Department of Agricultural Research (DAR) of Myanmar, which was originally co-signed in 2013 and extended with an addendum in 2018. Previous surveys have indicated that the diversity of the traditional crops of inland Chin State are on the verge of lost, and in the present survey, we focused on plant resources of the mid-south areas of Chin State, including Madupi District. Based on the findings of a previous short survey conducted by Ohm Mar Saw *et al*. (2019) in 2018, we focused on areas surrounding the Madupi Township during the agricultural off-season to collect PGRs and associated information. We collected PGRs mainly from the Mindat Township (Mindat District), Madupi and Retzua Townships (Madupi District), and Hakha Township (Hakha District) and a few PGRs from the Pale Township (Yinmabin District, Sagaing Region) and Pyinmana Township (Naypyidaw Union Territory). A total of 178 plant samples were collected which belonged to the following families: Amaranthaceae (five samples), Apiaceae (two), Araceae (four), Brassicaceae (11), Cucurbitaceae (26), Dioscoreaceae (two), Fabaceae (43), Lamiaceae (13), Malvaceae (11), Pedaliaceae (two), Poaceae (42), Rubiaceae (one), Solanaceae (13), and Zingiberaceae (three). The collected PGRs were divided into two subsets – one to be investigated

and conserved at the DAR Seed Bank of Myanmar and the other at the NARO Genetic Resources Center of Japan. Interviews with locals revealed that the vernacular names of selected crop plants were similar within a given Township in Chin State but often differed between the Townships. A 2005 field study on wild rice varieties of Chin State reported the occurrence of foxtail millet, and we anticipated finding this millet and were able to collect eight seed samples. However, none of these was viable in a germination test, and this indicates an ongoing genetic erosion of plant genetic resources in the study area.

KEY WORDS: Myanmar, Chin State, plant genetic resources, traditionally grown crops, genetic erosion

Introduction

Chin State is located in western Myanmar and bordered domestically by Sagaing Region to the north, Magway Region to the east, and Rakhine State to the south. It shares international boundaries with the Mizoram State and Manipur State of India to the west and Chattogram (Chittagong) District of Bangladesh to the southwest. It is a hilly and mountainous state which is less densely populated and has a limited transport infrastructure compared with plain areas of the country.

In this paper, we describe a joint Myanmar–Japan field study conducted in February 2019 to survey plant genetic resources (PGRs) mainly in Chin State of Myanmar. Similar joint surveys in Chin State have previously focused on traditional crop varieties during and after the Seed Bank Project of the Union of Myanmar (1997–2002) (https://www2.jica.go.jp/en/evaluation/pdf/2001_0601822_3_f.pdf). These include the technical cooperation schemes by the Japan International Cooperation Agency (JICA) for collecting food legumes from the northern parts of the State in 2002 (Tomooka *et al*. 2003), surveying wild rice populations in 2005 (Uga *et al*. 2006), and collecting vegetables from the southern parts in 2006 (Saito *et al.* 2006) and 2017 (Ohm Mar Saw *et al.* 2018). Considering this, Uga *et al.* (2006) commented that "It is noteworthy that foxtail millet, *Setaria italica* (L.) P. Beauv. ssp. *italica*, and finger millet *Eleusine coracana* (L.) Gaertn. ssp. *coracana* were widely grown at mountainous areas at the altitude 1,000 m or more in Chin State."

After surveying the PGRs in Kachin and Chin States in November 2017, Ohm Mar Saw *et al.* (2018) highlighted the importance of traditional crop diversity in the hilly and mountainous areas of Myanmar and stated that "slash-and-burn cultivation fields in both areas are expected to harbor large amounts of agro-biodiversity, and ethnodiversity needs to be systematically surveyed as soon as possible." They also reported that "Recent cultivation of cash crops such as elephant foot yam and coffee, may have almost replaced traditional cultivation of those millets." If we compare the statements from the two reports mentioned above, we can assume that the changes that occurred over the 12 years (2005–2017) indicate a widespread genetic erosion promoted by rapid social modernization and economic liberalization which accompanied the democratization of Myanmar. Therefore, it is essential to survey PGRs in inland Chin State as early as possible. To this end, we planned a joint Myanmar–Japan field study in February 2019 that involved a collaborative initiative between the Genetic Resources Center (GRC) of the National Agriculture and Food Research Organization (NARO) of Japan and the Biotechnology, Plant Genetic Resources and Plant Protection Division of Department of Agricultural Research (DAR) of Myanmar. The field study was implemented as a part of the PGRAsia (Plant Genetic Resources in Asia) project (https://sumire.gene.affrc.go.jp/pgrasia/research_en.php), which was allocated by the Ministry of Agriculture, Forestry and Fisheries to NARO.

We primarily focused on the PGRs of the mid-south region of Chin State, including Madupi District. This selection was based on the opinion that these areas have conserved traditional crop diversity, as indicated by the findings of the aforementioned previous field studies conducted in Chin State and also of those undertaken in the adjacent Sagaing Region (Domon *et al*. 2015a, 2015b; Min San Thein *et al.* 2017; Naito *et al.* 2017); the realization that PGR samples from this region require urgent investigation also affected our selection. We anticipate that PGRs from these areas would be useful materials for future crop improvement and should be conserved in gene banks within the public domain. Additionally, we intended to obtain information on the vernacular names and utilization of both crops and non-crops based on ethnobotanical point of view.

Methods

Our field survey team comprised of Tomotaro Nishikawa (TN, team leader), Ohm Mar Saw (OMS), and Makoto Kawase (MK). We assembled at the Seed Bank of DAR at Yezin, Nay Pyi Taw and entered Chin

State via Nyaung-U town in Mandalay Region using a robust 4 × 4 vehicle. Initially, we surveyed PGRs in the Mindat Township (Mindat District) and Madupi and Retzua Townships (Madupi District) in the mid-south region of Chin State. The Paletwa Township located west-southwest of Mindat District could not be surveyed due to the concurrent political instability of the region. Alternatively, we surveyed Hakha District to the north of Madupi District (Map 1).

Because the survey was conducted during the winter, we rarely observed standing crop plants. Hence, we visited the houses of farmers and local agricultural marketplaces and interviewed the locals to gain information on traditional crops, cultivation practices, and utilization of agricultural produce, particularly cereals, legumes, and vegetables, as well as herbs and spices. We collected plant material as PGRs and recorded crop names, village names, sources of the plant material, cultural practices, sowing and harvesting months, geographical characteristics, and topography. Global positioning system (GPS) information was recorded at each waypoint during the survey using the GPS logger application–Geo Tracker ver. 3.3.0 (https://geo-tracker.org/), installed on a ZenFone 3 (smartphone (ZE520KL, ASUS_Z017DA; ASUSTeK Computer Inc.). For altitude measurements, using a device with a small antenna (i.e., a smartphone) may not provide accurate results; hence, the altitude at each waypoint was estimated through Google Earth (Google Inc.) using the relevant waypoint information. For this paper, the names of towns and villages were spelled according to local informants, and when necessary, these were corrected using publicly available information provided by the Myanmar Information Management Unit (MIMU), which serves the UN Country Team and Humanitarian Country Team under the management of the UN Resident and Humanitarian Coordinator (https://data.humdata.org/organization/mimu).

During our interviews with the locals at 11 sites, we showed the interviewees the photographs of 73 selected crops, to know the vernacular names. Though we attempted to write these names down using the Roman alphabet, in the case of communities with indigenous writing systems based on the Roman alphabet, we requested our interviewees to write the crop names using their own scripts.

Ethnobotanical information was collected in accordance with the Code of Ethics of the International Society of Ethnobiology (ISE) (http://www.ethnobiology.net/what-we-do/core-programs/ise-ethics-program/code-of-ethics/).

During the present study, we collected eight samples of foxtail millet seeds from the Retzua and Hakha Townships and sowed them in pots filled with sterilized soil for seed multiplication in a greenhouse of the Faculty of Agriculture, Tokyo University of Agriculture in 2019.

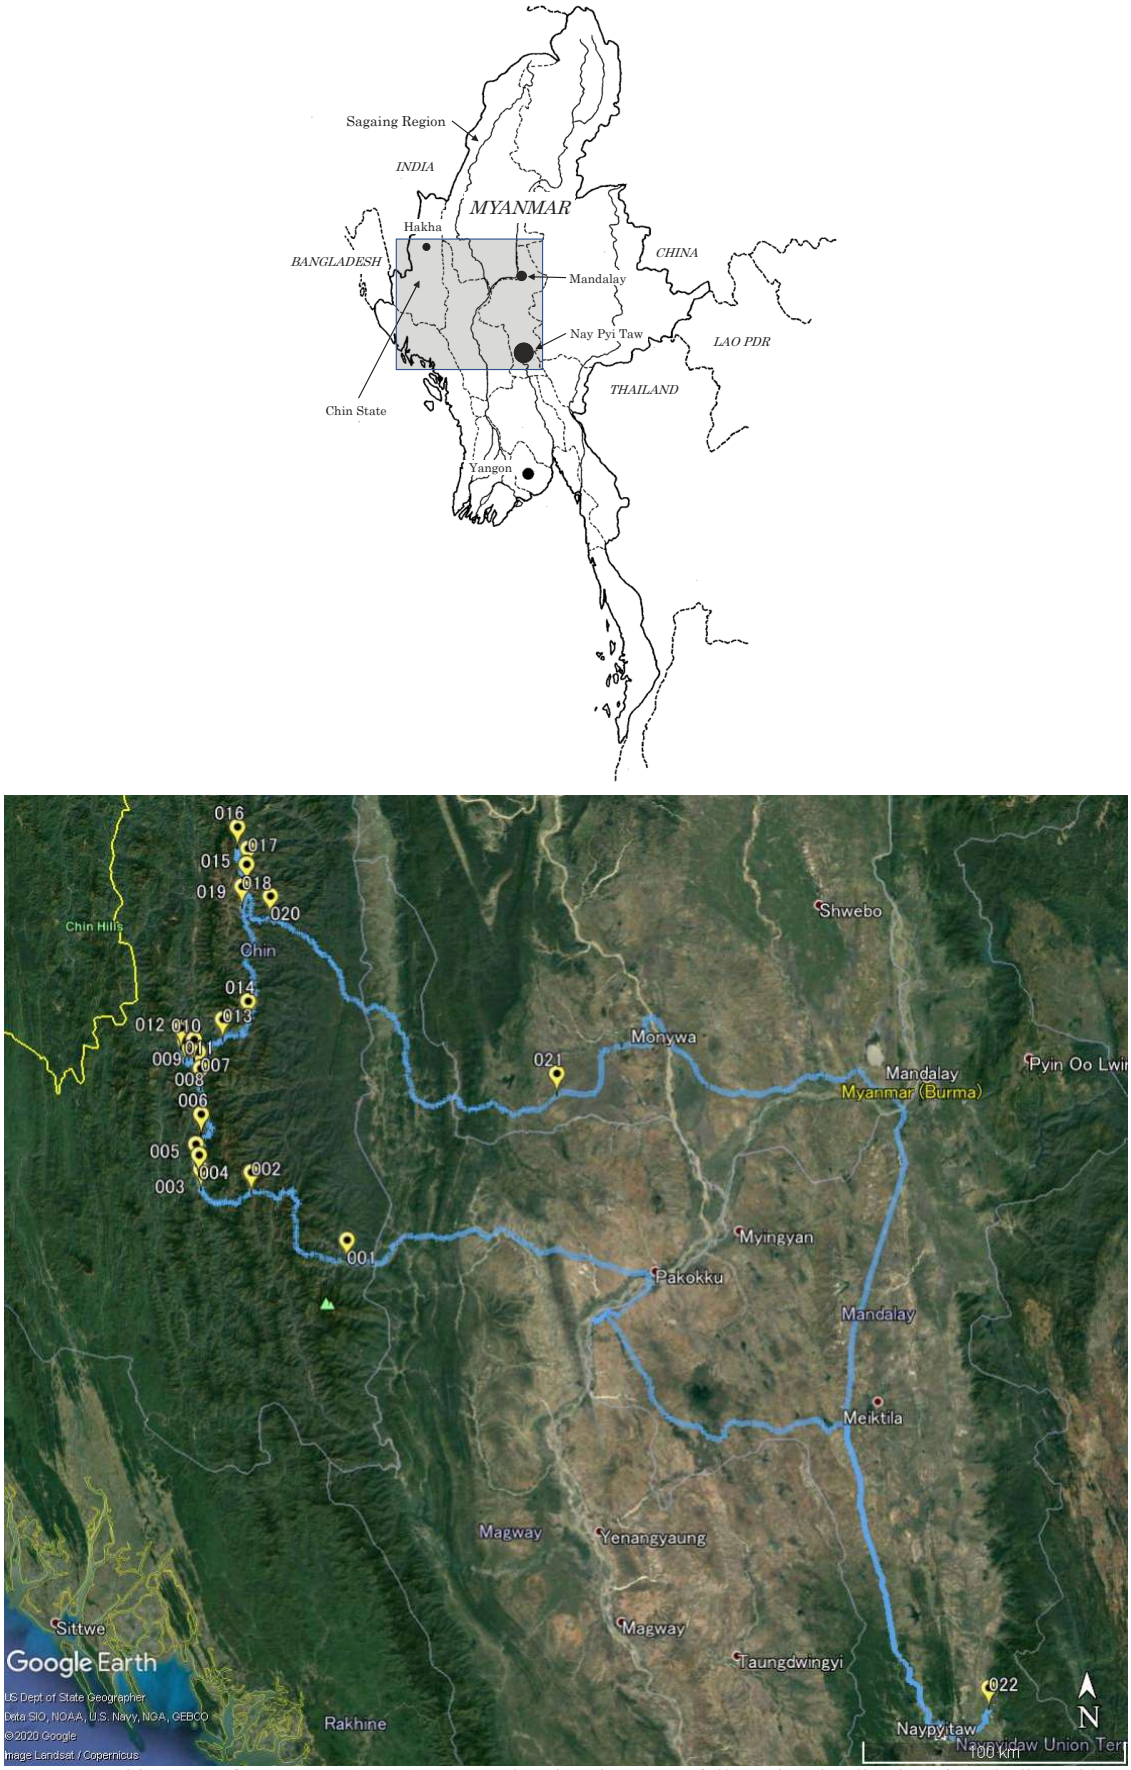

Map 1. A white map of Myanmar (upper). A map showing the routes followed and collection sites (indicated by waypoints) surveyed during the field study in Chin State, Myanmar, in February 2019 (lower), which correspond to the square with a half-tone dotting in the upper white map.

However, none of the seeds germinated. We investigated the viability of these seeds using 100-grains of each of the eight samples. As controls, we used the seeds of a foxtail millet landrace, COL/MYANMAR/2005/NIAS/26, which was collected in 2005 from Lamtuk village (Hakha Township, Chin State) (Uga *et al.* 2006), maintained in cold dry storage at approximately 5 °C for 12 years, and subsequently grown in a greenhouse at the University of Tsukuba and harvested in 2017 (seed stock no. 2017-095-1). The control and eight collected seed samples were stored in sealed boxes containing silica gel in a refrigerator at approximately 4 °C. Before sowing, the seeds were sterilized first using 70% ethanol for 1 min and then sodium hypochlorite solution (containing approx. 1% available chlorine) for 5 min. The seeds were then rinsed twice with deionized water, soaked in 1% Tween 80 (polyoxyethylene 20 sorbitan monooleate) solution for 30 s, treated with 15% hydrogen peroxide for 1 min, and rinsed twice with deionized water. The sterilized seeds were then placed on moist filter papers in Petri dishes and incubated at 30 °C. The germination test was conducted by Katsumasa Niwa (KN) and MK at Tokyo University of Agriculture, Atsugi.

Results and Discussion

During the present survey, we visited villages, cultivation fields, houses of local farmers, and local marketplaces, where we interviewed the locals to gain information on traditionally grown crops and other beneficial plants (non-crops). Our survey coincided with the agricultural off-season for commonly cultivated summer crops (except for *Brassica* species); hence, we witnessed very few standing crops. The locals kindly provided us with samples of local crop varieties; information on associated cultivation practices, vernacular names, and usage; and other relevant details. However, most of the samples were provided from farm storage, and we could not obtain information related to the geography, stoniness, soil texture, and drainage of the cultivation sites.

We collected plant samples from the following areas: Mindat Town (waypoint 001), Layseik village (002) of Mindat District, Madupi Town (003), Phaneng village (004), Nga Leang village (005), and Khua Ngang village (006) in Mindat Township, and Siango village (007), Hring Thang Khna village (008) Retzua town (010), Sawti village (011), Long Thang Tlang village (012), Sha Shi village (013), and Ai Ka village (014) in Rezua Township, Madupi District, Hakha City (015), Chun Cung village (016), Hniar Lawn village (017), Loklung village (018 & 019), and Zokhua village (020) in Hakha Township, Hakha District, Chin State. In addition, we collected plant materials at Tha Pyay Gone village (021) in Pale Township of Yinmabin District in the Sagaing Region and Yezin village (022) in Pyinmana Township in Naypyidaw Union Territory (Map. 1).

Plant genetic resources collected

We collected a total of 178 plant samples during our field study which are listed in Table 3. These consisted of 178 samples belonging to the following families: Amaranthaceae (five), Apiaceae (two), Araceae (four), Brassicaceae (11), Cucurbitaceae (26), Dioscoreaceae (two), Fabaceae (43), Lamiaceae (13), Malvaceae (11), Pedaliaceae (two), Poaceae (42), Rubiaceae (one), Solanaceae (13), and Zingiberaceae (three) (Table 2). Among these, four, 46, 75, and 50 samples were collected from the Mindat, Madupi, and Rezua Townships and Hakha District of Chin State, respectively. Additionally, two samples were collected from the Pale Township (Sagaing Region), while one was from the Pyinmana Township (Naypyidaw Union Territory) (Table 3).

The collected samples comprised a large number of leafy and fruit vegetables, cereals such as rice and millet, edible legumes, root and tuber crops, and herbs and spices, all of which were grown traditionally and primarily for self-consumption rather than for selling in commercial markets. The collected samples also contained some non-traditional crops such as coffee — *Coffea arabica* L. and elephant foot yam — *Amorphophallus paeoniifolius* (Dennst.) Nicolson, which were probably introduced to the region more recently during the democratization of Myanmar. This may have been facilitated by improvements in the regional transport infrastructure, such as the widening and renovation of trunk roads. Although these developments have provided multiple benefits to the local agricultural communities, they may have also heralded significant changes in the types of cultivated crops. We reaffirm the findings of Ohm Mar Saw *et al.* (2018) that the cultivation of traditional crops is giving way to the newly-introduced cash crops, such as elephant foot yam and coffee, in some instances.

We divided the samples collected by us into two subsets: the samples in one subset were investigated and conserved at the Seed Bank of the Plant Biotechnology, Plant Genetic Resources and Plant Protection Department, DAR, Yezin, Nay Pyi Taw Union Territory, Myanmar, for further research and crop improvement; those in the other subset was transferred to Japan to be conserved at the NARO GRC at Tsukuba, Japan, under

Table 2. A summarized list of the materials collected in Chin State, Myanmar, in February 2019

Family scientific species name	English name	Family-wise subtotal	No. of collected materials
Amaranthaceae		5	
Amaranthus tricolor L.	edible amaranth		1
Celosia argentea L.	plumed cockscomb		1
Chenopodium bengalense (Lam.) Spielm. ex Steud.	tree spinach		3

Vigna unguiculata (L.) Walp.	cowpea		8

a Standard Material Transfer Agreement (SMTA) for the International Treaty on Plant Genetic Resources for Food and Agriculture (ITPGRFA) of the United Nations Food and Agriculture Organization. A phytosanitary certificate was issued by the Plant Protection Office of DOA, Yangon, Myanmar. All plant materials in the second subset were inspected by the Plant Quarantine Inspectors of the Ministry of Agriculture, Forestry and Fisheries (MAFF), Japan at the Narita Airport. Because rice is one of the prohibited imports listed in the Plant Protection Act of Japan, we obtained a special permit issued in the name of the Minister, MAFF, Japan, to introduce these seeds into Japan. Moreover, rice samples were cultivated in an isolated greenhouse of the NARO GRC under the supervision of a plant quarantine officer.

Table 2. (Continued).

Family scientific species name	English name	Family-wise subtotal	No. of collected materials
Lamiaceae		13	
Elsholtzia blanda (Benth.) Benth.	elshortzia basil		3
Ocimum basilicum L.	basil		4

Zingiber officinale Rosc.	ginger		1
Total			178

Observations in Chin State

Mindat (waypoint 001) is a small town located at the entrance of Chin State when accessing from Pakokku. We observed a range of different vegetables and food legumes (Photo 1) being traded at the Mindat Myoma Zay marketplace, where agricultural produce was brought from neighboring villages. We noticed a recently constructed reinforced concrete building which was a sign of rapid modernization in the area and was not present in November 2018. Nevertheless, traders at the marketplace continued to sell agricultural products and other food commodities from the more traditional bower-style stalls and on-street stores.

After crossing several passes at elevations of over 2,000 m above mean sea level, where *Rhododendron* trees were often observed (Photo 2), we visited Madupi (waypoint 003; alternatively spelled Matupi), a small town located amid the Chin Hills. Agricultural products transported from surrounding villages were being sold at the Madupi marketplace (Photo 3). In addition to common leafy and fruit vegetables, seeds of different types of food legumes [*Vigna umbellata* (Thunb.) Ohwi & Ohashi, *V. unguiculata* (L.) Walp. Group Unguiculata, *Phaseolus vulgaris* L., *P. lunatus* L., and *Pisum sativum* L.] were available at the marketplace at wooden bower-style stalls and on-street stores. These crops are widely grown in several areas in Myanmar. It was interesting to note that the dried panicles of the elsholtzia basil (*Elsholtzia blanda* (Benth.) Benth.) (Photo 4) and seeds of perilla (*Perilla frutescens* (L.) Britton var. *frutescens*) were also available at the marketplace. These plants are often grown in the hilly and mountainous areas of Myanmar and neighboring Nagaland, India (Domon *et al*. 2015a) and are used as herbs and spices in various

Photo 1. Vegetables harvested from neighboring villages being sold at the Mindat Myoma Zay marketplace in Mindat town (waypoint 001), Chin State

Photo 2. *Rhododendron* flowers were seen in the high mountain areas between the towns of Mindat and Madupi in Chin State

preparations. The seeds of *P. frutescens* are used to extract the oil. Furthermore, we also found young pods of *Cajanus cajan* (L.) Millsp. and *Parkia speciosa* Hassk. being sold as vegetables (Photo 5).

On our subsequent visit to three villages in the Madupi Township — Phaneng village (waypoint 004), Nga Leang village (005), and Khua Ngang village (006) — we collected traditional varieties of rice (*Oryza sativa* L.), maize (*Zea mays* L.), food legumes [*V. umbellata*, *V. unguiculata*, and *Psophocarpus tetragonolobus* (L.) DC.], root and tuber crops (*Dioscorea alata* L. and *Zingiber*

Photo 3. A range of food materials produced in neighboring hill villages being sold at a marketplace in Madupi town (waypoint 003), Chin State

Photo 4. Elshotzia basil, *Elsholtzia blanda* (Benth.) Benth., sold at a marketplace in Madupi town (waypoint 003), Chin State

Photo 5. Young pods of *Parkia speciosa* Hassk. (left) are also sold as vegetables at a marketplace in Madupi town (waypoint 003), Chin State

Photo 6. Harvested panicles of tree spinach, *Chenopodium bengalense* Spielm. ex Steud., are hung beneath the eaves of houses in Khua Ngang village (waypoint 006), Madupi Township, Chin State

Photo 7. Species of *Ocimum* are important spices in the hilly and mountainous areas of Myanmar. The plants shown here were hung on the kitchen wall of a house in Ai Ka village (waypoint 014), Retzua Township, Chin State

officinale Rosc.), and Cucurbitaceae crops (*Luffa cylindrica* M. Roem, *Cucumis sativus* L., and *Cucurbita maxima* Duch.), all of which are commonly grown throughout Myanmar. The less extensively cultivated traditional crops such as tree spinach (*Chenopodium bengalense* Spielm. ex Steud.) (Photo 6) and elsholtzia basil were also collected from here. However, we could not locate any finger millet (*E. coracana* ssp. *coracana*) or foxtail millet (*S. italica* ssp. *italica*) in Madupi Township, which Uga *et al.* (2006) found being cultivated in abundance for food and brewing during a 2005 survey. We also observed the cultivation of recently introduced cash crops — elephant foot yam and coffee — at several sites, including Khua Ngang village (006).

Moving northward from Madupi, we visited Siango village (waypoint 007) and Hring Thang Khna village (008 & 009), Retzua town (010), Sawti village (011), Long Thang Tlang village (012), Sha Shi village (013), and Ai Ka village (014) in the Retzua (alternatively spelled Rezua) Township, Madupi District. These small communities are scattered in hilly areas and, owing to the poor regional transport infrastructure, tend to be

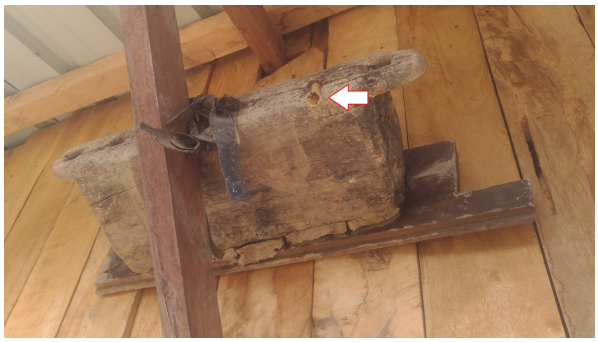

Photo 8. Traditional keeping of stingless bees is practiced in Hring Thang Khna village (waypoint 008), Retzua Township, Chin State. The type of stingless bee shown here constructs a trumpet-shaped entrance (indicated by an arrow) to the hive.

self-sufficient and economically isolated. In common with Madupi Township, we found that various leafy and fruit vegetables, as well as rhizomatous crops, were widely cultivated in this region. Although cash crops such as elephant foot yam have been introduced to the region, the locals experience difficulties in transporting the harvested material to markets in the large towns

Photo 9. Traditional keeping of stingless bees is practiced in Hring Thang Khna village (waypoint 008), Retzua Township, Chin State. The type of stingless bee shown here constructs an embanked entrance (indicated by an arrow) to the hive.

Photo 10. Pasturing of domesticated cattle, mithun (or gayal) (*Bos frontalis* Lambert), in Retzua Township, Chin State

Photo 11. A vegetable store at the marketplace in Hakha City (waypoint 015) selling a range of fresh vegetables and high-quality cereals and food legumes, some of which may have been brought from large cities such as Yangon and Mandalay

Photo 12. A glass of wine made from foxtail millet grains brewed using a traditional method

and cities where this produce is typically consumed. Moreover, samples of foxtail millet and finger millet were collected from farm storage, which implied that these crops were cultivated until recently. Tree spinach, elsholtzia basil, basil (*Ocimum basilicum* L.) (Photo 7), and perilla were grown by farmers for domestic consumption.

A further noteworthy observation was the continuation of traditional beekeeping practices, with stingless bees (Hymenoptera: Apidae: Meliponini) being reared in several villages in Retzua Township. We observed two different types of stingless bees: one that constructed a trumpet-shaped entrance to the hive (Photo 8) and the other that manufactured an embanked entrance (Photo 9); however, we did not identify the species. A similar keeping of stingless bees has been observed over the border in India at Udhiaguri village (Baksa district, Bodoland Territorial Region of Assam state) and Tusom Christian village (Ukhrul district, Manipur state) (Kawase, unpublished observation). We also observed domesticated cattle (mithun or gayal, *Bos frontalis* Lambert) pastured in the Retzua Township (Photo 10), which is also reared in the hilly areas of the Sagaing Region, Myanmar, bordering Northeast India and Bhutan.

We also visited Hakha City (waypoint 015)

Photo 13. Burning plants for the slash-and-burn cultivation on a hillside in the suburbs of Hakha City

Chun Cung village (016), Hniar Lawn village (017), Loklung village (018 & 019), and Zokhua village (020) in the Hakha Township, Hakha District. Hakha City is the capital of Chin State and shops at the Hakha City marketplace sell a variety of fresh vegetables, cereals, and food legumes produced in the neighboring villages; other food commodities might come from large cities such as Yangon and Mandalay (Photo 11). The agricultural products traded here were similar to those available in the Townships of Mindat, Madupi, and Retzua, but were more abundant. We observed plants being burned for locally practiced slash-and-burn

cultivation on a hillside in the suburbs of Hakha City (Photo 12).

Our visit to Hakha City unexpectedly coincided with a period of Chin National Day celebrations, as a part of which, an exposition attended by State Counsellor Ms. Aung San Suu Kyi was being held at the city's Hakha Stadium. There were well-decorated areas within the stadium where the DOA and other public and private sector organizations exhibited their products and inventions and provided relevant information. Notably, in a remote corner of the stadium, young members of the Students' Union of Hakha College operated a drinks booth where we were offered wine made from traditionally brewed foxtail millet grains (Photo 13). We hope that such initiatives would stimulate further interest in studying the past through reviving traditional practices and products.

Among the three townships to which we paid short visits, the people of Retzua maintained the cultivation of the most extensive variety of traditional crops, including foxtail millet, finger millet, and perilla. Though we could not cover the entire township due to our short itinerary, we recommend re-surveying the Retzua Township during the harvest season (October-November) and collecting PGRs from standing crops rather than seeds that have been stored for long-term. Furthermore, we were unable to gain access to the isolated township of Paletwa which is a potential target area for future surveys.

Vernacular names of crops in the surveyed areas

To verify the recognition of the crops cultivated in the surveyed areas, we showed the locals the same set of printed photographs of 73 crops that had been used in previous trips and recorded the associated vernacular names used at particular sites. These records could be considered a preliminary inventory of the vernacular names of crops in the regions in which different indigenous languages and/or dialects are spoken. Although these records undoubtedly include some names that were either misheard or less appropriately transliterated because of our unfamiliarity with the local phonetic systems, we believe that they would provide a useful reference for future studies. During our interviews with the locals, we came to realize that it is generally difficult to ascertain exact crop names that correspond directly to a specific taxonomic species, as the folk taxonomy does not always reflect the taxonomic conventions of systematic botany. Moreover, the names our interviewees provided us after inspecting the photographs depended on their perception of a given crop image. For example, in cases of plants they were unfamiliar with, they tended to suggest the name of a plant they believed the image to be of or provide second-hand information. Moreover, they often hesitated to say, "we don't know", because they might be afraid to disappoint us. Complicating the matter., most of the individuals that we interviewed lived in multilingual societies and attempted to provide names in as many languages as they knew.

Despite the difficulties, we succeeded in compiling a list of the vernacular names of 42 of the 73 crops for each township (Table 4), which represents the crops for which we obtained vernacular names in 6 or more sites (of the total 11 sites wherein interviews were conducted). Names previously collected from the Mindat and Madupi Townships in November 2017 were included in the list for comparative purposes (partially published by Ohm Mar Saw *et al*. 2018). The names for each crop in the Madupi (6 sites) and Retzua (5 sites) Townships showed considerable similarities within the sites in each township, whereas the names for the same crop were often significantly different in different townships. Due to the limited information obtained from the townships of Hakha (3 sites) and Mindat, we could not make useful comparisons; hence, we highlight the need for more extensive interviews in these townships. In some cases, crops were referred to by the names same as those used in the Burmese language spoken by the Bama people (Burmese people in the strict sense) or variations thereof. These names are indicated as "as Bama" and "like Bama," respectively, in Table 4. Burmese is the lingua franca of Myanmar and is taught in schools throughout the country, and we found that most of the locals we interviewed with could understand Burmese. Furthermore, it is possible that a few names have been derived from, or influenced by, the English, Hindi, and/or Mizo languages. However, despite the preliminary nature of our findings, we believe that our information would serve as a reference to succeeding researchers and younger generations of local communities to gain a wider and more accurate understanding of traditional crops and their cultivation.

Detailed data on the vernacular names collected in the present field survey, together with those obtained in other relevant field studies, are being compiled and will be published elsewhere in its entirety.

Genetic erosion of crop resources in Chin State

The findings of the preliminary study conducted by Ohm Mar Saw *et al.* (2018) provided evidence to indicate the ongoing erosion of crop plant genetic resources in Chin State. Communities inhabiting the widely dispersed

Table 5. Seed viability of eight collected samples of foxtail millet (*Setaria italica* ssp. *italica*) revealed by a germination test

villages of inland Chin State continue to cultivate a considerable variety of traditional crops under the slash-and-burn agriculture and terraced paddy field systems as well as in backyard gardens. In many cases, however, these crop plants are on the verge of extinction due to the recent introduction of cash crops and improvements in regional transport links that are progressively connecting remote villages with large cities, both physically and economically. Such profound social and economic changes are inevitable and will gradually improve the living standards of local communities. As a consequence, however, it seems equally inevitable that the traditional crops and varieties that have sustained the local life and indigenous culture for generations will be lost gradually.

In this field study, we surveyed parts of Mindat Township, Madupi Township and Hakha Township in Chin State and successfully collected a variety of PGRs. Unfortunately, the eight samples of foxtail millet seeds, which we collected from the Retzua and Hakha Townships and sowed for purpose of seed multiplication, did not germinate (Table 5). Among these seed samples, we did not anticipate high germinability in three samples obtained from marketplaces in the Hakha Township because these had already been dehulled for sale. However, we had anticipated the remaining seed samples to germinate because these were sourced directly from farm storage. Contrastingly, the control seeds from the 2017-095-1 seed stock, which had been preserved dry at around 4 °C for more than 3 years after the harvest, showed a high germination rate (97%). The results indicate that foxtail millet is an orthodox seed plant that can retain viability for long periods when preserved under appropriate conditions. This further suggests that all the foxtail millet seeds collected from the Retzua and Hakha Townships had lost their viability during post-harvest storage and confirms genetic erosion.

From a wider perspective on the results of our study, we conclude that less extensively grown crops should not be ignored, as we cannot reliably predict which crops, varieties, or genotypes might be of value to crop improvement in times of global climate change. In this context, much of Chin State remains relatively unexplored and warrants timely in-depth surveys, preferably during the harvest season. Moreover, it is also of considerable importance to undertake appropriate characterization and evaluation measures for PGRs collected in various programs, including PGRAsia.

Acknowledgements

We are sincerely grateful to the locals of the surveyed areas for their kindness and hospitality. We particularly thank them for comprehensively explaining their agricultural practices and providing samples of cultivated crops and other useful plants. We also wish to express our sincere gratitude to the authorities at the Ministry of Agriculture, Livestock and Irrigation (MOALI), Republic of the Union of Myanmar, for their proactive cooperation. The field study was conducted as a cooperative research activity under the "Memorandum of Understanding for Collaborative Research Project on

Genetic Resources for Food and Agriculture" between the Department of Agricultural Research (DAR), Ministry of Agriculture and Irrigation (now reorganized as the Ministry of Agriculture, Livestock and Irrigation), Myanmar and the National Institute of Agrobiological Sciences (NIAS; reorganized as the National Agriculture Research Organization, NARO), Japan, which were signed bilaterally in 2014 and extended with a mutually agreed Addendum in 2017. We would like to express our cordial thanks to Dr. Naing Kyi Win, Director General, DAR, MOALI, Daw Nwe Nwe Yin, Director, BPGRPPD, DAR. We thank the Seed Bank staff for processing collected plant genetic resources. We are obliged to Dr. Ye Tint Tun, Director General of the Department of Agriculture (DOA), MOALI, for his kind assistance and advice. We are indebted to all the DOA officers at Mindat District Office, Madupi Township Office, Retzua Township Office, and Hakha District Office of the DOA for their kind assistance during our local visits and interviews with local inhabitants. Finally, we are particularly grateful to U Win Naing for his safe driving on risky roads in hilly and mountainous areas.

This work was supported by MAFF commissioned project study on "A Collaborative Research Project on Characterization and Evaluation of Plant Genetic Resources for Food and Agriculture (PGRAsia)" Grant Number JPJ007117).

和文摘要

本報告書は 2019 年 2 月にミャンマー国チン州で実施した植物遺伝資源に関する日本・ミャンマー共同探索調査の報告である．本調査は，農林水産省委託プロジェクト PGRAsia の一部として計画され，ミャンマー国農業研究局と農研機構の間の合意に基づいて実施された．ミャンマー・日本両国の協力によるこれまでの食料農業植物遺伝資源の収集調査の結果，チン州内陸部の伝統的作物の多様性が絶滅の危機に瀕していることが示唆されており，マドゥピ県を含むチン州の中南部を対象地域に決定した．ミンダッ県ミンダッ郡区，マドゥピ県マドゥピ郡区とレッツア郡区，ならびにハカ県ハカ郡区で植物遺伝資源を収集調査した．また，チン州以外ではサガイン地方域インマビン県パレ郡区とネピドー連邦域ピンマナ郡区でも植物遺伝資源を収集した．本調査の結果，合計 178 点の植物遺伝資源を収集した．それらは，ヒユ科（5 点），セリ科（2），サトイモ科（4），アブラナ科（11），ウリ科（26），ヤマノイモ科（2），マメ科（43），シソ科（13），アオイ科（11），ゴマ科（2），イネ科（42），アカネ科（1），ナス科（13），およびショウガ科（3）であった．収集された遺伝資源は 2 つのサブセットに分け，ひとつはミャンマーのシードバンクで保存され，もうひとつは日本の農研機構の遺伝資源センターで保存される．地元の人々へのインタビューを通じて作物の方名（現地での呼称）を聞き取ったところ，各郡区内ではかなり似かよっているが，郡区と郡区の間ではしばしば異なる傾向があることが分かった．今までの調査で多様性が期待されたアワは 8 点収集できたが，全て発芽せず，近年急速にコンニャクやコーヒー等の換金作物の導入とともに遺伝的浸食が急速に進んでいることが明らかになった．
