1. Introduction

The importance of atmospheric greenhouse gases on climatic warming has brought attention to global sinks and sources of carbon in terrestrial ecosystems (Mooney *et al.*, 1987; Post, 1990; Schlesinger, 1990; Tans *et al.*, 1990; Oechel and Billings, 1992; Harden *et al.*, 1992; Oechel *et al.*, 1993). Northern ecosystems (tundra and boreal forests) comprise 13% of the earth's land area but account for as much carbon storage as 22% of the terrestrial plant and soil organic matter, most of which (83%) is found in seasonally thawed layers or trapped in permafrost (Miller, 1981).

Northern ecosystems may be important for global carbon balance because climatic warming deepens the active layer of permafrost which causes erosion and eventual loss of permafrost over a great portion of Arctic tundra and boreal forest (Oechel and Billings, 1992). Consequently, Arctic hydrology makes the upper soil layers dry and the decomposition rate of organic matter in soil increases (Oechel and Billings, 1992). Furthermore, the rate at which carbon accumulates in terrestrial ecosystems depends on the vegetation and climate, and on the presumed sensitivity of soil carbon accumulation or loss to climatic change (Miller *et al.*, 1983; Billings, 1987). As a result, much of the carbon stored in the active soil layer and permafrost is released into the atmosphere, thereby increasing and exacerbating CO₂ caused warming (Billings *et al.*, 1982) and changing the micrometeorology of the tundra. Elevated atmospheric CO₂, along with changed micrometeorology and changed nutrient availability affect plant communities and vegetation. In the event of global warming and its attendant ecosystem and climatic changes, there is considerable uncertainty as to whether the northern ecosystem will act as a CO₂ sink or not.

In the 1970's Coyne and Kelley (1971, 1975) reported the characteristics of the micrometeorology and CO₂ flux over an area of tundra at Barrow in Alaska, as part of a study of the US International Biosphere Program (IBP). Coyne and Kelley (1971) measured wind profiles at several heights, CO₂ concentrations and air temperature profiles up to 16 meter in height, soil temperatures, solar radiation, and some other factors at the IBP site area, and then revealed that the Arctic tundra was a sink of atmospheric CO₂. Recently, Oechel *et al.* (1993) measured CO₂ flux at a coastal Arctic tundra during 1991 and 1992 using a chamber method (see Photograph 12) and found that the Arctic tundra acts as a source of CO₂ today. They compared their CO₂ flux data with those of the early 1970's determined by Coyne and Kelley (1971, 1975) in the IBP program. Although, the present micrometeorological characteristics

at the site were not investigated precisely, the comparison of the micrometeorological data obtained at two different times with a twenty year difference can improve the understanding of the characteristics of Arctic tundra and the climatic warming.

This study was carried out to examine whether the coastal Arctic tundra acts as a sink or source today, with comprehensive measurements during the summer in 1993. The observation site was the same coastal Arctic tundra at Barrow, Alaska, used in the 1970's by Coyne and Kelley (1971, 1975). A micrometeorological survey and flux measurements were made using aerodynamic, heat budget, and eddy correlation methods. The micrometeorological data were obtained over almost all of the summer season of 1993 at Barrow. These results are valuable not only for further study of the Arctic ecosystem but also for assessing the contribution of tundra vegetation to global warming. Therefore, the data is reported here along with the analysis on the changes of CO₂ flux over the 20 years and the differences in CO₂ flux between wet tundra and polygonal dry tundra in the Arctic tundra ecosystem will be done in the near future.

2. Location and methods

2.1 Sites

The observation sites are located at two sites over coastal Arctic tundra near Barrow (71°18'N, 156°47'W, with a population of approximately 4000), the northernmost city in Alaska facing the Chukchi Sea. The Arctic coastal tundra is characterized by low relief, and dominated by ice-wedge polygons, shallow, oriented lakes and drained basins (Bunnell *et al.*, 1975). Over views of the Arctic tundra are shown in Photograph 1 during the thawing period of spring and Photograph 2 in mid-summer. The former measurement site is named the IBP site, and the latter the Central Marsh site. The locations of the two sites are shown in Fig. 1.

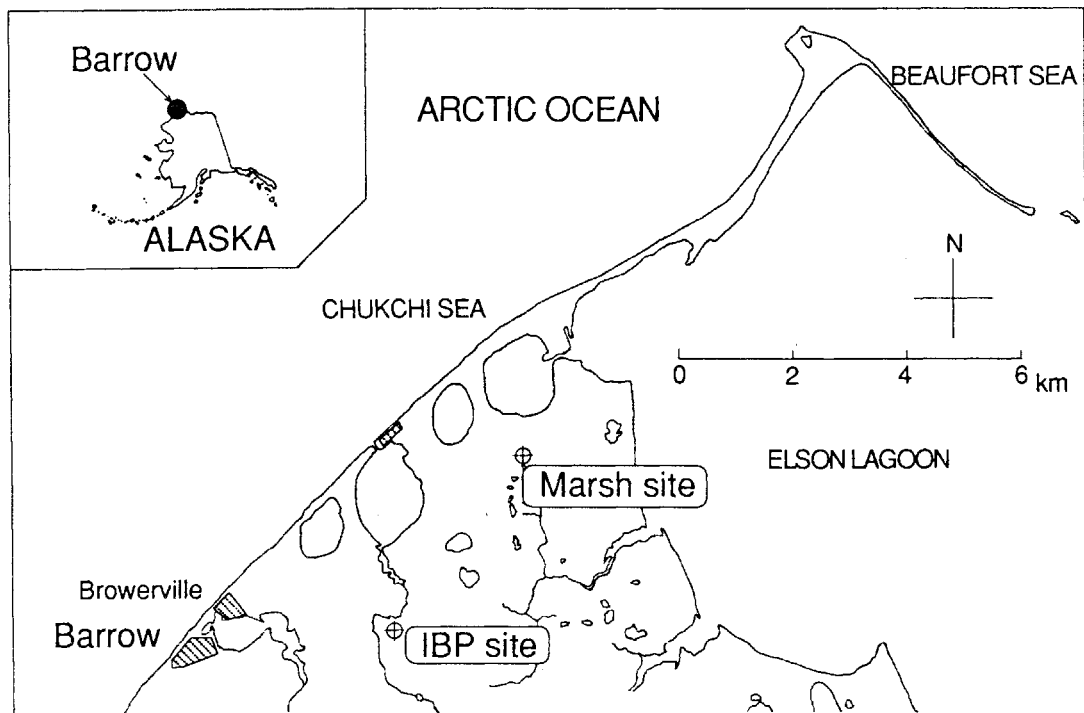

Fig. 1 Map of contiguous Alaska (inlet) and details of an area adjoining to the measurement sites (the IBP and the Central Marsh sites).

The IBP site is located 2.5 km east of the edge of Browerville village near Barrow city and 2.5 km from the southeast coast of the Chukchi Sea. This site is the same experimental site as that of the US International Biosphere Program (IBP) Tundra Biome intensive site (71°17'68"N, 156°41'33"W) of the 1970's. The measurement point was set at about 300 m south of the edge at a small creek that runs from Footprint Lake which is located south of the site. Flat tundra stretches over several kilometers in all directions from the measurement point except for the small creek, and an uneven polygonal pattern (polygon) 20 to 40 cm in height is scattered over some parts of the ground surface around the measurement point. The polygon around the IBP site is shown in Photograph 3. Sufficient fetch length was obtained of more than 1 km in the direction between the northeast and northwest and 300 m to the north, which was sufficient to evaluate the fluxes of momentum, heat and gases using micrometeorological techniques. There was an unpaved road about 0.8 km east of the measurement point but with very little traffic, and there was no serious influence of human activities to disturb the measurement except for CO₂ discharged from a gasoline power generator.

The Central Marsh site (hereinafter Marsh site) is located 7 km northeast of Barrow, 2 km southeast of the Chukchi Sea shore, and 2 km west of Elson Lagoon. The Central Marsh is a dried lagoon with an elliptic shape of approximately 3 km in major axis and 1.5 km in minor axis, and is now a flat and wet lowland. A wide bank rim (ridge) about 2 m in maximum height and 100 m in width surrounds the marsh. The measurement point (71°19'27"N, 156°37'09"W) was about 300 m from the nearest northeast bank-edge. The fetch of the Marsh site was more than 1 km to most directions except the northeast bank, and the influence of human activities on the measurement was as little as that at the IBP site.

2.2 Instruments and Setting them up for measurements

Field measurements were carried out at both sites using towers. A typical schematic view of measurement at the IBP site is illustrated in Fig. 2, and the setting conditions at the IBP site are shown in Photographs 4, 5, and 6 in mid-June, mid July and late-August. At the IBP site, most measurements were carried out from June 15 to July 18 and from August 9 to August 25, and some elements were measured between July 19 and August 8. While at the Marsh site, almost the same elements as at the IBP site were measured between July 20 and August 8. The measured elements, instruments and their

mounting conditions at each site are listed in Table 1 for each period.

The EB750 power generator (AC120 V, 60 Hz, 750 W : Honda , Tokyo, Japan) was used to supply power for measurement at the IBP site. The generator was placed more than 100 m north of the tower by June 21, and was then moved to more than 200 m north to avoid CO₂ contamination from the generator. While at the Marsh site, we used the commercial power supply from the field observatory of the National Geography Service, which was about 400 m from the measurement tower.

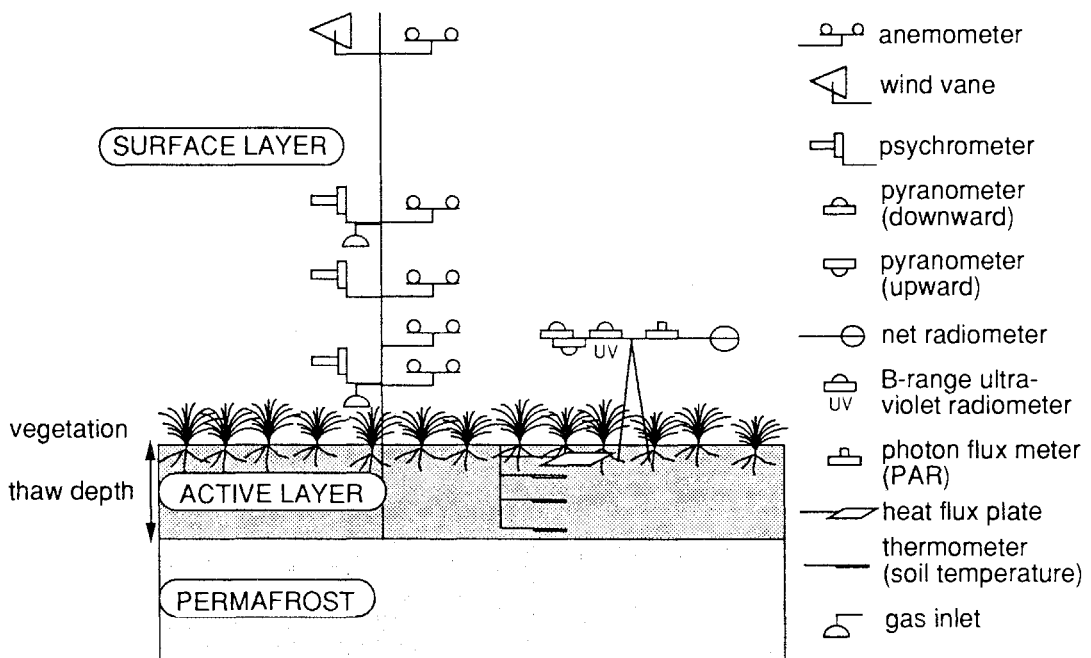

Fig. 2 Schematic illustration of the setting up of instruments at tundra.

Table 1 Measured elements and their set-up heights at the field.

Element	Symbol	Height (m)	Sensor
Wind speed (highest)	U1	4.7	Cup anemometer
Wind speed	U2	2.0	Cup anemometer
Wind speed (middle)	U3	1.2	Cup anemometer
Wind speed	U4	0.7	Cup anemometer
Wind speed (lowest)	U5	0.3	Cup anemometer
Wind direction	WD	4.7	Wind Vane
CO2 Concentration (higher)	CO2-H	2	NDIR CO2 analyzer Inlet height
CO2 Concentration (lower)	CO2-L	0.3	NDIR CO2 analyzer Inlet height
Solar Radiation	R _s	1.0	Thermopile Pyranometer
Reflection of R _s	R _{su}	0.9	Thermopile Pyranometer
Net Radiation	R _n	1.2	Net Radiometer
Photosynthetic Active Radiation	PAR	0.3	Photon sensor
Ultra Violet Intensity	UVb	0.3	UV radiometer
Dry bulb Temperature (high)	Ta1	2	Ventilated psychrometer (PT-100)
Dry bulb Temperature (middle)	Ta2	1.2	Ventilated psychrometer (PT-100)
Dry bulb Temperature (lower)	Ta3	0.3	Ventilated psychrometer (PT-100)
Wet bulb Temperature (high)	Tw1	2	Ventilated psychrometer (PT-100)
Wet bulb Temperature (middle)	Tw2	1.2	Ventilated psychrometer (PT-100)
Wet bulb Temperature (lower)	Tw3	0.3	Ventilated psychrometer (PT-100)
Soil Temperature	Ts1	0.01	Thermocouple (Type-T)
Soil Temperature	Ts2	0.05	Thermocouple (Type-T)
Soil Temperature	Ts3	0.10	Thermocouple (Type-T)
Soil Temperature	Ts4	0.20	Thermocouple (Type-T)
Soil Heat flux	G1	0.005	Heat flow plate
Soil Heat flux	G2	0.005	Heat flow plate

1) Micrometeorological components

The vertical wind profile was measured using 5 cup-anemometers (014A, Campbell Scientific Inc., Logan, USA) which were mounted at up to 4.7 m in height with a horizontal boom extending 0.5 m from the tower. Wind direction was measured with a wind vane (024A, Campbell Scientific Inc., Logan, USA) at the same height as the top anemometer. Dry-bulb and wet-bulb temperatures were measured using ventilated psychrometers (hand-made and calibrated with Asmann's psychrometer) with a platinum resistance thermometer at three different heights. The other two sets of psychrometers consisting of a T-type thermocouple sensor (Copper and Constantan, 0.31 mm diameter) were mounted at two different

heights on the other site. Soil temperatures at two to four depths were measured with the T-type thermocouple. Measured depths were 1, 5, 10, 20 cm below the surface, but the depth varied with the observation sites because of the limitation of the terminal numbers of the data logger. Depth is shown in the data tables for each measured site. Soil heat flux was measured with two thermopile-type heat flux plates (MF-9, Eko Instruments Co., LTD, Tokyo Japan), and both sensors were buried at 0.5 cm in depth and the average value of the two was obtained.

Downward solar radiation (R_{sd}) and reflected solar radiation (R_{su}) were measured with thermopile-type pyranometers (MS-62, Eko Instruments Co., LTD., Tokyo, Japan), and each was mounted horizontally but facing opposite directions, and this set was used at the IBP site. The other thermopile-type pyranometers (PCM-03, Kipp & Zonen, the Netherlands) were used only at the Marsh site. Net radiation was measured continuously at the IBP site using a thermopile-type ventilated net radiometer (MF-11, Eko Instruments Co., LTD., Tokyo Japan), while a non-ventilated sensor (Q-6, Campbell Scientific, Inc., Logan, USA) was partly used at the Marsh site. Photosynthetic active radiation (PAR) was measured with a silicon photo diode-type photon flux meter (ML-020P, 400-700 nm in wavelength, Eko Instruments Co., Ltd., Tokyo, Japan). B-range ultraviolet radiation (UV-B, 280-315 nm in wavelength) was also measured with a silicon photo diode-type UV-B meter (MS-210W, Eko Instruments Co., LTD., Tokyo, Japan) during the latter half of the measurement period.

2) Carbon dioxide concentrations

The carbon dioxide (CO_2) concentration was measured using a non-dispersive infrared gas analyzer (ZFU1, Fuji Electric Co. Ltd., Tokyo Japan). Air at the two tower heights were sampled through each Teflon tube with a polyfluo filter (PF050, Toyo Filter, Ltd., Tokyo, Japan) at flow rates of $1.0 \text{ dm}^3/\text{min}$. Sampled air at each height was sent continuously to the switching solenoid valve (NCV-3, Takasago electric Inc., Tokyo, Japan), and one of them was alternately sent to the cell of the CO_2 analyzer. Water vapor included in the sample was removed using a semi-permeable drier (ZBJ0250, Fuji Electric Co. Ltd., Tokyo, Japan) before the inlet of the cell. The solenoid valve was controlled every 70 seconds interlocking with data acquisition by a data logger (21X, Campbell Scientific, Inc., Logan, USA). This system was used at both the IBP and Marsh sites.

Another non-dispersive infrared gas analyzer (ZFP9, Fuji Electric Co. LTD., Tokyo, Japan) was

also used at the IBP site from July 19 to August 8. In this system, the air flow rate was $0.6 \text{ dm}^3/\text{min}$, and the solenoid valve was switched every 60 seconds. Water vapor within the sampled air was removed by the membrane filter installed in the analyzer. However, the control of the switching valve by the data logger (CR10, Campbell Scientific, Inc., Logan, USA) failed for most of the measurement period due to the wet and cold conditions at the IBP site.

Calibration of both analyzers was made at any interval during the measurement periods using two levels of CO_2 standard gases (299.4 ppm and 473.6 ppm).

2.3 Periods of data collection

The preliminary measurement was carried out over snow-covered tundra near the Climatic Monitoring and Diagnostic Laboratory (CMDL), National Ocean & Atmospheric Administration (NOAA) located at the east of Central Marsh in Barrow from June 8 to 10. The circumstances of the measurement over snow covered tundra are shown in Photographs 7 and 8. These preliminary measurement data are not listed in this data book.

Measurement at the IBP site was carried out from June 15 to August 25, and at the Marsh site from July 19 to August 9. Most data were obtained at the IBP site, because there was not enough equipment for both sites. During the measurement period at the Marsh site, some sensors were moved from the IBP site to the Marsh site, therefore wind speed and wind direction were not measured and the number of measurements of depth of soil temperature and ventilated psychrometer were fewer than in other periods.

In the summer season, the summer time system is used in Alaska and the Alaska Standard Time (AKST) was 8 hours later than Greenwich Mean Time (GMT). In this paper the time is specified in AKST to show the data with time.

3 Acquisition of data and quality control

3.1 Mode of processing input signals from sensors

A digital data logger 21X (Campbell Scientific Inc., Logan, USA) with a relay multiplexer (AM416) was mainly used to collect both meteorological and CO₂ concentration data at both observation sites. Micrometeorological data were sampled every 70 seconds and the 10 minute average was recorded, because the AM416 of the platinum resistance thermometers did not work at the same interval as the interval timer SDM-INT8 of the cup anemometers in the field. Another digital data logger CR10 (Campbell Scientific, Inc., Logan, USA) was used at the 1BP site on July 19 and August 8. In this data acquisition system, data were collected every 10 seconds and averaged every 10 minutes and then memorized. Data were subsequently processed in the laboratory after each run.

3.2 Quality control of data and calibration

Data stored in the data logger were checked for errors, and then the numerical values were converted to physical values with dimension. Correction of data was carried out for 10 minutes averages, then averaged again for every 30 minutes, the 30 minute average being specified as both periods from 10 to 40 minutes (specified as 00 of each hour in the tables) and from 40 to 10 minutes (specified as 30 of each hour in the tables).

1) Temperature data

There was no correction for soil temperature data obtained using thermocouples, because there was no significant difference among the sensors and the reference temperature of the logger was thought to be almost constant in the shielded wooden box. Platinum resistance thermometers were used as the sensors of the ventilated psychrometers which were calibrated at the National Institute of Agro-Environmental Sciences (NIAES) before and after the field measurement, and differences among the sensors were checked by setting them at the same conditions (location, height, direction) in the field. The field comparisons of the sensors were made three times from June 8 to August 25. The calibration factor for each sensor and the modified factor obtained by field checks were used in the calculation. Though, the thermocouple was also used as the sensors of ventilated psychrometers, the calibration and correction of these psychrometers were made in the same way as those with platinum resistance thermometers.

In the data tables, Ta1, Ta2 and Ta3 represent the 30 minute average air temperatures (°C) obtained by the ventilated psychrometers at each level. Ts1, Ts2, Ts3, and Ts4 represent the 30 minute average soil temperatures (°C) obtained by the thermocouples.

2) Humidity

Saturation water vapor pressures (mb) were calculated using the Goff-Gratch formulation (List, 1971) for wet bulb temperatures at each measured height. The formations used in the calculation for liquid water and ice were as follows:

$$\log e_{ws} = -7.90298 \left(\frac{Ta}{T} - 1 \right) + 5.02808 \log \frac{Ta}{T} - 1.3816 \cdot 10^{-7} \left(10^{11.344 \left(1 - \frac{T}{Ta} \right)} - 1 \right) + 8.1328 \cdot 10^{-3} \left(10^{-3.49149 \left(\frac{T}{T} - 1 \right)} - 1 \right) + \log (1013.246) \quad (1)$$

$$\log e_{is} = -9.09718 \left(\frac{To}{T} - 1 \right) - 3.56654 \log \frac{To}{T} + 0.876793 \left(1 - \frac{T}{To} \right) + \log (6.10714) \quad (2)$$

where,

e_{ws} = saturation vapor pressure of pure ordinary liquid water (mb)

e_{is} = saturation vapor pressure of pure ordinary water ice (mb)

T = absolute temperature (K)

Ta = steam point temperature (373.16 K)

To = ice point temperature (273.16 K)

Vapor pressures e_w (mmHg), relative humidity RH (%), absolute humidity of the air AH (g/m³) were calculated using the following formulations.

$$e_w = 0.750617 (e_{ws} - 0.000660 (1 + 0.00115 t_w)) P (t_d - t_w) \quad (3)$$

$$RH = 100 \frac{e_w}{e_{wsd}} \quad (4)$$

$$AH = 1.06 \frac{e_w}{(1 + 0.00367 t_d)} \quad (5)$$

where,

e_{wsd} = saturation vapor pressure for dry bulb temperature (mmHg)

t_d = dry bulb temperature (°C)

t_w = wet bulb temperature (°C)

P = atmospheric pressure (mmHg)

We did not measure the air pressure P , therefore, the standard value of 760 mmHg was used in the calculation of equation (3). In the data tables, AH1, AH2 and AH3 represent the 30 minute average absolute humidity (g/m^3) in the air at each level calculated as mentioned above. RH1, RH2, and RH3 represent the 30 minute average relative humidity of the air obtained by formulation (4).

3) Radiation and soil heat flux

Data on net radiation, downward solar radiation and its reflection from the surface, were corrected using each calibration factor. Data on soil heat flux obtained using two heat flow plates were corrected in the same way as was radiation, then the averaged value of the two was determined as the soil heat flux (G , W/m^2) listed in the data tables. There was no correction owing to the heat storage between the surface and the heat flow plates because the thickness of the soil over the heat plate was very thin.

In the data tables, Rsd and Rsu represent the 30 minute average downward and upward (reflected) solar radiation (W/m^2), respectively. Rn represents the 30 minute average net radiation, UVb represents the 30 minute average flux density of the B-range ultra violet radiation (W/m^2), and PAR represents the 30 minute average photon flux density of photosynthetic active radiation ($\mu\text{E}/\text{sm}^2$) at the field obtained by each sensor mentioned in section 2.2.

Albedo was calculated using downward solar radiation Rsd and its reflection Rsu. Because the incidence angle of the sun's beams is low over the Arctic tundra, the accuracy of the pyranometers lessened with the increase of the incident angle. Thus, the reflection of solar radiation Rsu was greater than the downward solar radiation Rsd in some cases, therefore calculated albedo values over 0.5 were omitted from the data tables.

4) Wind speed and direction

Five cup anemometers were used in the field. The differences among the anemometers were checked in the wind tunnel of NIAES (the test section was 2, 2, 9 m in width, height, length, respectively and the wind speed range was 0.3 - 25 m/s) and in the field in the same way as the psychrometers. At first, a data sampling interval was designed every 10 seconds for the 5 anemometers simultaneously with

the interval timer SDM-INT8, but SDM-INT8 did not work with AM416 in the field. Therefore, wind speed was measured by counting the pulse of each anemometer every 10 seconds alternately, thus determining the wind profile every 70 seconds. Data were corrected using modified calibration factors obtained in the field. Field calibrations of all sensors were carried out three times at the same height over the tundra during the observation period.

In the data tables, U1 to U5 represents the 30 minute average wind speed (m/s) at each level. Owing to the different sampling timings of wind speed (every 70 seconds) the inversion of the wind profile was sometimes observed, therefore only three levels of wind speed are listed in the data tables. WD represents the 30 minute average value of wind direction, a number was specified from 0 to 360 degrees for the clockwise rotation from north - east - south - west - north.

5) Aerodynamic parameters

In order to investigate micrometeorological conditions, aerodynamic parameters were evaluated. The following is an outline of the methods used.

In the boundary layer, the wind profile over the vegetation or the ground surface can be expressed as formula (6) under neutral atmospheric conditions.

$$u(z) = \frac{u_*}{\kappa} \ln \frac{(z-d)}{z_0} \quad (6)$$

where $u(z)$ is the average wind speed at any height z , u_* is the friction velocity, κ is the von Karman's constant (0.41), d and z_0 are zero plane displacement and the roughness length of the surface. In the turbulent boundary layer over vegetation, momentum flux τ was given by equation (7).

$$\tau = -\rho Km \frac{du}{dz} = \rho u_*^2 = -\rho uw \quad (7)$$

Where ρ is the density of air, Km , the eddy diffusivity of momentum. According to the mixing-length hypothesis by Prandtl, uw is obtained as equation (8). Where lm is a mean mixing length and is proportional to κ and z in the turbulent boundary layer (Arya, 1988).

$$uw = -lm^2 \frac{du}{dz} \frac{du}{dz} \quad (8)$$

Thus, Km is also expressed using wind profiles as equation (9), and an integrated formula to calculate the momentum flux is given as follows (Denmead, 1970).

$$Km = \kappa^2 z^2 \frac{du}{dz} = \kappa^2 \frac{u}{\ln(z/z_0)} = \kappa^2 \frac{z \Delta u}{\ln(z_2/z_1)} \quad (9)$$

$$\frac{\tau}{\rho} = \kappa^2 \frac{\Delta u \Delta u}{\{\ln(z_2/z_1)\}^2} = Df \Delta u \quad (10)$$

where Δu is the difference in the wind speed between the heights of z_1 and z_2 , and Df is diffusive (diffusion) velocity for the momentum between the two heights. Then, diffusion velocity Df can be obtained from the next formula under neutral atmospheric conditions:

$$Df = \frac{\kappa^2 (u_2 - u_1)}{(\ln(z_2 - d) - \ln(z_1 - d))^2} \quad (11)$$

u_1 and u_2 are mean wind speeds at height z_1 and z_2 , respectively and d and other aerodynamic parameters such as z_0 and u_* can be obtained by the regression line of the logarithmic wind profile (Harazono *et al.*, 1990, 1993), using the following equations, where a and b are coefficients of the regression equation.

$$\ln(z - d) = a u(z) + b \quad (12)$$

$$u_* = \kappa / a \quad (13)$$

$$z_0 = \exp(b) \quad (14)$$

If the atmospheric stability is negative, Df has to be corrected according to the stability function (Thom, 1975). In this study, the Richardson number Ri was used to check atmospheric stability, and the flux was modified using a corrected function with specific function $F(Ri)$.

$$Dfc = \frac{\kappa^2 (u_1 - u_2)}{(\ln(z_1 - d) - \ln(z_2 - d))^2} F(Ri) \quad (15)$$

The corrected diffusion velocity Dfc was obtained from formula (15) according to Thom (1975), and the specific function $F(Ri)$ of the Richardson Number Ri is given in formula (16). T_{a1} , T_{a2} , T are the air temperatures at heights z_1 and z_2 , and mean temperature (unit K), respectively.

$$Ri = \frac{g}{T} \frac{(T_{a1} - T_{a2})(z_1 - z_2)}{(u_1 - u_2)^2} \quad (16)$$

$$F(Ri) = (1 - 16Ri)^{0.75} \quad -0.2 < Ri < 0 \quad (17-a)$$

$$F(Ri) = (1 - 5Ri)^2 \quad 0 < Ri < 0.2 \quad (17-b)$$

In the data tables, z_o (cm), u (m/s), Ri and Dfc (cm/s) are listed, having been calculated according to the above analysis. Df in the data table is a modified value for gas transportation (the same as Dfc), and it will be useful to evaluate CO_2 flux, water vapor (latent heat) flux, and sensible heat flux in the following analyses. Although, there is some uncertainty in the correction equations (17-a,b), the Df value may be modified slightly in further studies.

6) Carbon dioxide concentration

Calibration of the infrared CO_2 gas analyzer was carried out using two standard gases in the field and laboratory in Barrow. The levels of the standard gases used were 299.4 ppm and 473.6 ppm. Unfortunately, at the IBP site, we had to stop the generator almost once a week in order to change the oil. Output levels of the CO_2 analyzer shifted slightly after restarting the generator, therefore some CO_2 data obtained after the maintenance of the generator were modified.

Background CO_2 data were provided by NOAA's Climatic Monitoring and Diagnostic Laboratory (CMDL) located to the east of Central Marsh in Barrow. Because there are great differences in averaging, sampling heights, sampling equipment and sampling intervals between the background data by NOAA and the measured data over the tundra, there might be some differences in the concentration levels listed.

4. Additional reference data

4.1 Background CO₂ concentration data by NOAA

Hourly background CO₂ data from the micrometeorological measurement period are also listed in the data tables (B-CO₂). These data were prepared by NOAA's Climatic Monitoring and Diagnostic Laboratory (CMDL). The air at 15 m high tower was sampled and analyzed by an NDIR analyzer (ULTRAMAT, Siemens, Germany). The averaging periods in hours are specified as the beginning of the hour, for example, hour 5 corresponds to 5 AM to 6 AM AKST. Therefore, the averaged periods of background CO₂ concentrations are different from those of measurements of the CO₂ concentrations over the tundra. A selection process has undertaken to distinguish "background" concentrations, that is, the values that CMDL believed were not contaminated by local sources or sinks of CO₂ were selected. The selection process depended on the station (Peterson *et al.*, 1986). The collected air sample, which was from a strict clean air sector, was as a defined wind direction between 20 and 110 degrees for Barrow. The standard deviation of the 1-minute average had to be less than 0.3 ppm, otherwise the hour gets a "V" (variable) flag. Also, the average change from one hour to the next is less than 0.25 ppm. Some data have additional codes, and there are a large number of possible codes, but the most common codes used in the tables are:

C - Weekly calibration of reference gases, no data available

I - Instrument malfunction, no data available

V - Large variability of CO₂ concentration within one hour

D - Hour-to-hour difference in concentration > 0.25 ppm

A - Automatic selection based on residuals from a spline curve

Details concerning the background data by CMDL/NOAA were reported by Peterson *et al.* (1986).

4.2 Monthly weather data from the National Weather Service

There is a first order National Weather Service (NWS) station located in the center of Barrow. Climate data listed in this data book were collected and compiled by Brown *et al.* (1994). Monthly data from June, July and August are shown in Tables 2, 3, and 4. Maximum and minimum temperatures were recorded automatically, and mean temperature was calculated from a max-min amplitude. Precipitation was recorded at 7 o'clock (AKST) on the next day, and the record period was different from temperature data. Wind speed was measured at the top of the station building which was more than 10 m in height, therefore the wind speed listed in the Tables 2 to 4 obtained at NWS/Barrow were higher than those obtained at 4.7 m high over the tundra.

The station is located in the center of the city and there are many buildings near the station. Temperatures in the city might have been higher than that over tundra because of the effects of urban climate in the data of NWS, especially in summer.

4.3 Thaw depth

Thaw depth was measured by striking an iron stick (diameter 8 mm) vertically into the ground to the permafrost table. Measurements were made almost every week for the IBP and Central Marsh sites. At the IBP site, we measured thaw depth at four different conditions on the ground, high center, low center, the rim (ridge) of the polygon and ice wedge (trough). The schematic illustration of the polygon is shown in Fig. 3 (after Patrick, 1978), At the Marsh site, measurements were carried out at both the upland (dry tundra) of the bank side and the lowland (wet tundra) of the basin. At each point, more than 10 samples of thaw depth were measured and the average was used for analysis. The trend of thaw depth is shown in Fig. 4 for the IBP site, in Fig. 5 for the Marsh site.

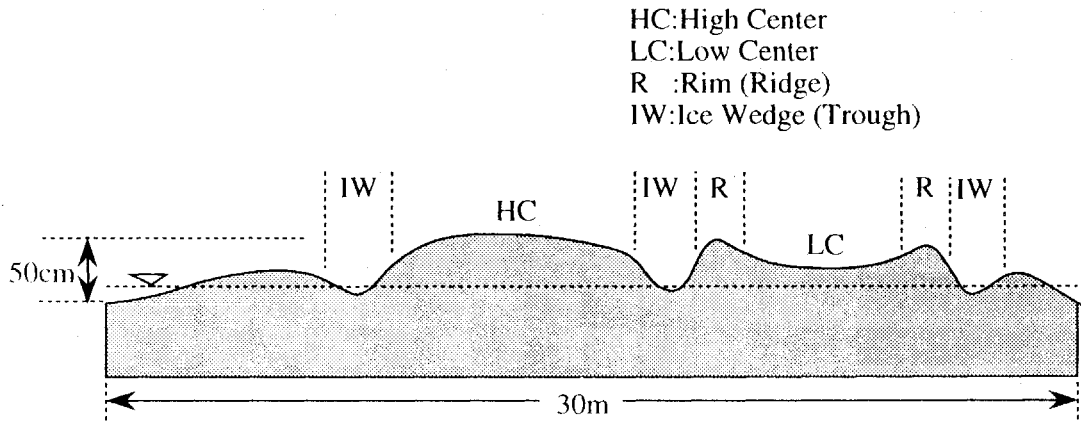

Fig. 3 The principal micro relief features of polygons at the IBP site (after Patric, 1978).

5. Notes on results

5.1 Field conditions during the measurement periods

The sun was above the horizon from the beginning of measurement till mid-August. More than 80% of the snow melted by June 10 at the Marsh site and by June 12 at the IBP site. However, snowfall was observed even in the morning in July and in the daytime in mid-August, and we had 3 cm of snow on August 15 (Photograph 9). Fog was often observed at both sites, especially in June and August. The beach of the Chukchi Sea was covered with ice floe till late June. After early July, ice floes left the beach, but sometimes came close to the beach with strong northerly winds.

According to a report of the first order National Weather Service (NWS) station located in the city of Barrow, July 1993 was the second warmest July on record, but August was cooler than usual (Brown *et al.*, 1994).

Vegetation at IBP site was a relatively dry coastal tundra community consisting of several species of dry heath, wet heath, and mist meadow (Bunnell *et al.*, 1975). At the beginning of the measurement (mid-June), there was no living grass but dead shoots whose average height was less than 10 cm (Photograph 4). Although, the density of the grass was low, the soil was covered with a moss carpet whose depth increased with thaw depth and with a maximum thickness of about 10 cm. Fresh leaves of grass germinated over the moss surface after late June, then grew up to about 25 cm in late July (Photograph 10). Thaw depth was different at the high center, low center, rim and ice wedge of the polygon. The former was deeper than the latter, and the maximum depth was 28 cm at the high center in early August, while that at the ice wedge it was 21 cm. The trend in thaw depth is shown in Fig. 4.

The vegetation at the Marsh site was a wet meadow tundra community, and the major plants around the observation site were some species of wet meadow and pond margin (Bunnell *et al.*, 1975). Some species of meadow germinated in the pond in late June and grew to about 15 cm in average height in late July, and to a maximum height of 25 cm in early August (see Photograph 11). Surface conditions at the measurement point were shallow puddles (pond), much wetter than at the IBP site. Thaw depth at the lowland was almost zero in June 8 and the permafrost dissolved up to a maximum depth of 29 cm in early August, while the maximum depth at the bank was 44 cm at the same time (Fig. 5).

5.2 Daily variations of heat budget components

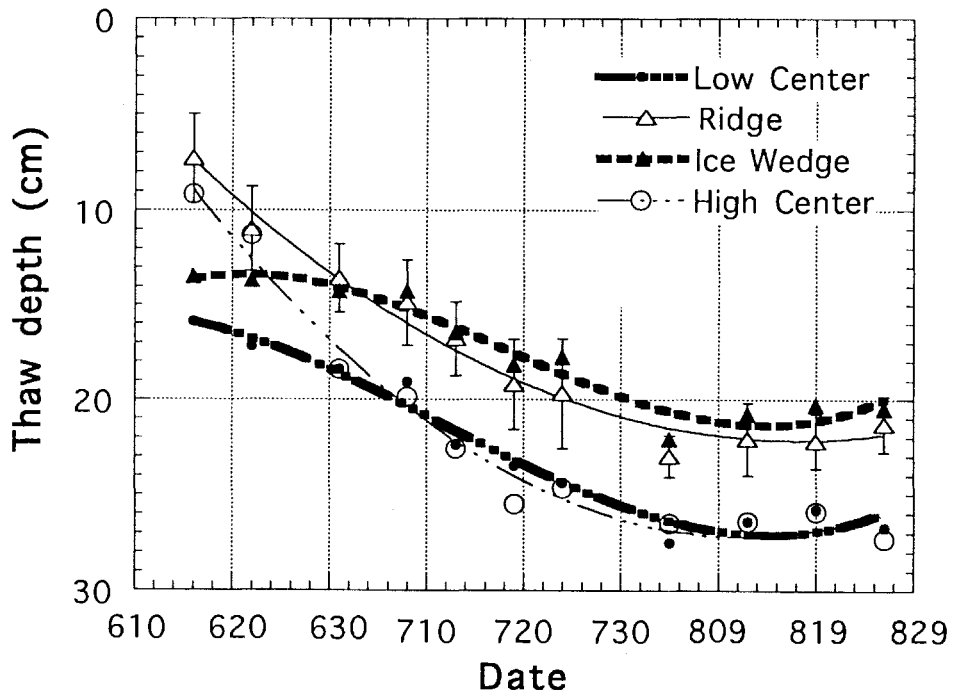

Fig. 4 Variations of thaw depth at the IBP site. Refer to Fig. 3 for characteristic surface features.

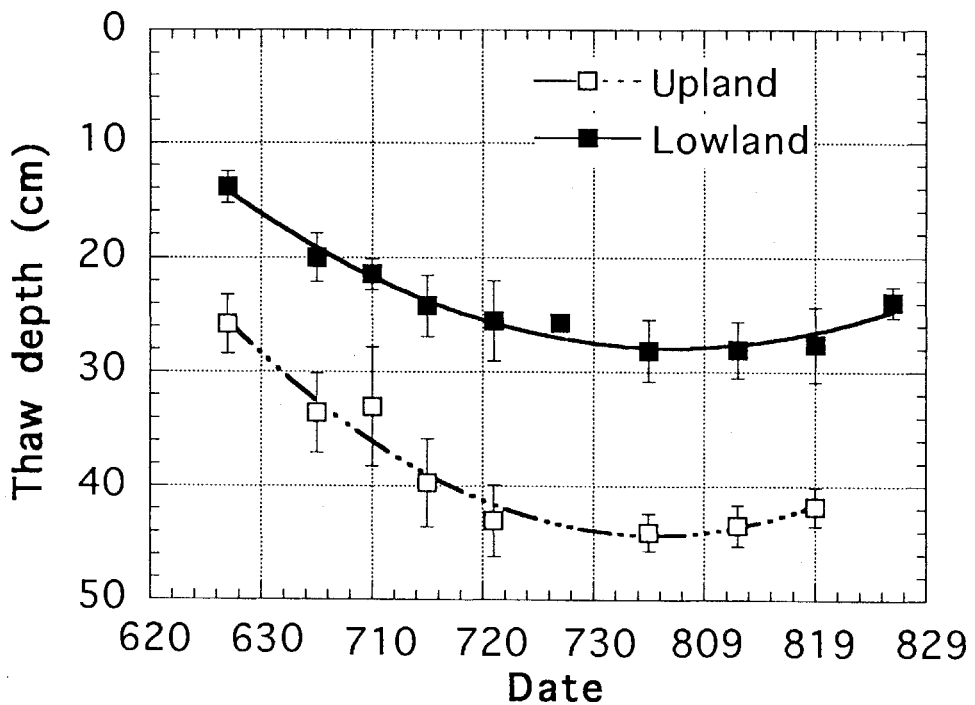

Fig. 5 Variations of thaw depth at the Central Marsh site.

1) Heat budget analysis

The heat budget of a ground surface is given by the equation,

$$Rn = H + lE + G \quad (18)$$

where Rn , H and lE are the net radiation, sensible heat flux and latent heat flux (l is the latent heat of the vaporization of liquid water and E is the evaporation rate), and G is the heat flux through the soil surface (W/m^2). In the turbulent boundary layer, the diffusion velocity of water vapor is assumed to be equal to that of heat (Monteith, 1973). The Bowen ratio, β is defined as the ratio of sensible to latent heat flux as the middle of equation (19). Thus β can be determined from the gradients of temperature and humidity as follows:

$$\beta = \frac{H}{lE} = \gamma \frac{\Delta T_a}{\Delta e_a} \quad (19)$$

where γ is the psychrometric constant, and ΔT_a and Δe_a are vertical gradients of air temperature and vapor pressure. Energy fluxes of H and lE can be determined using Bowen ratio β and measured values of Rn and G as follows:

$$H = \beta \frac{Rn - G}{1 + \beta} \quad (20)$$

$$lE = \frac{Rn - G}{1 + \beta} \quad (21)$$

2) Typical results of heat budget over the tundra at the IBP site

Fig. 6 shows the daily patterns of the heat budget components, Rn , lE , H and G at the IBP site in mid-June (a), late June (b), mid-July (c), late July (d) and early August (e).

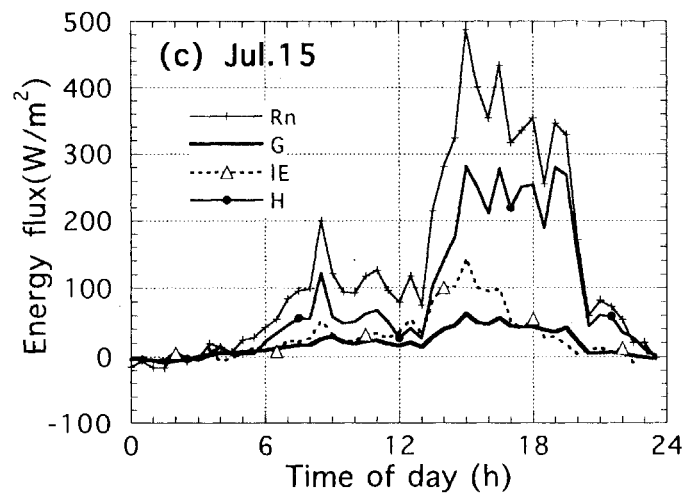

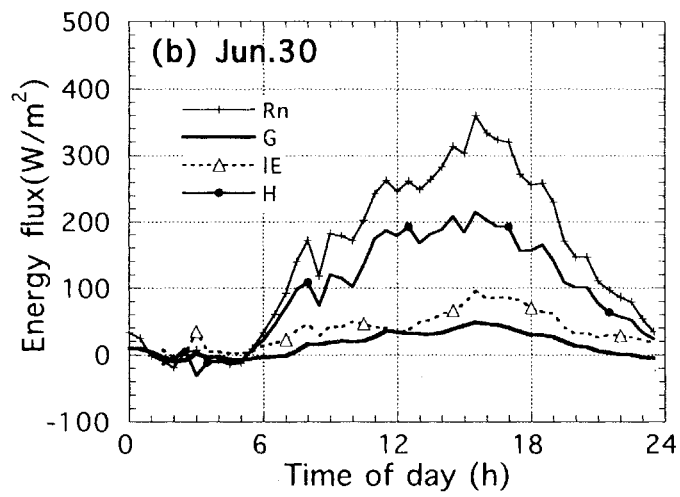

Before mid-July, the sensible heat flux H accounted for most of the net radiation Rn , and the contribution of latent heat flux to Rn was small. The wind with low temperatures and high humidity blew over the Arctic tundra frequently which caused high sensible heat flux. The contribution of H to Rn was about 75%, and that of lE was 12% in the earlier half period of measurement (from June 15 to July 17).

During the mid-summer (late-July) the daily maximum of the latent heat flux often exceeded

100W/m², and its contribution to R_n increases to 34%. The contribution of H was about 55%.

In the period of late-summer (from August) R_n decreased significantly which caused a decrease of H and G , though the level of lE was almost the same as that of mid-summer (about 3MJ/m² day). The contribution of lE to R_n was 44%, and that of H was 45%. The increasing trend of lE was caused by a deepening of the thaw depth as shown in Fig. 4 and Fig. 5.

The contribution of soil heat flux G to R_n was within 11-15% for each clear day.

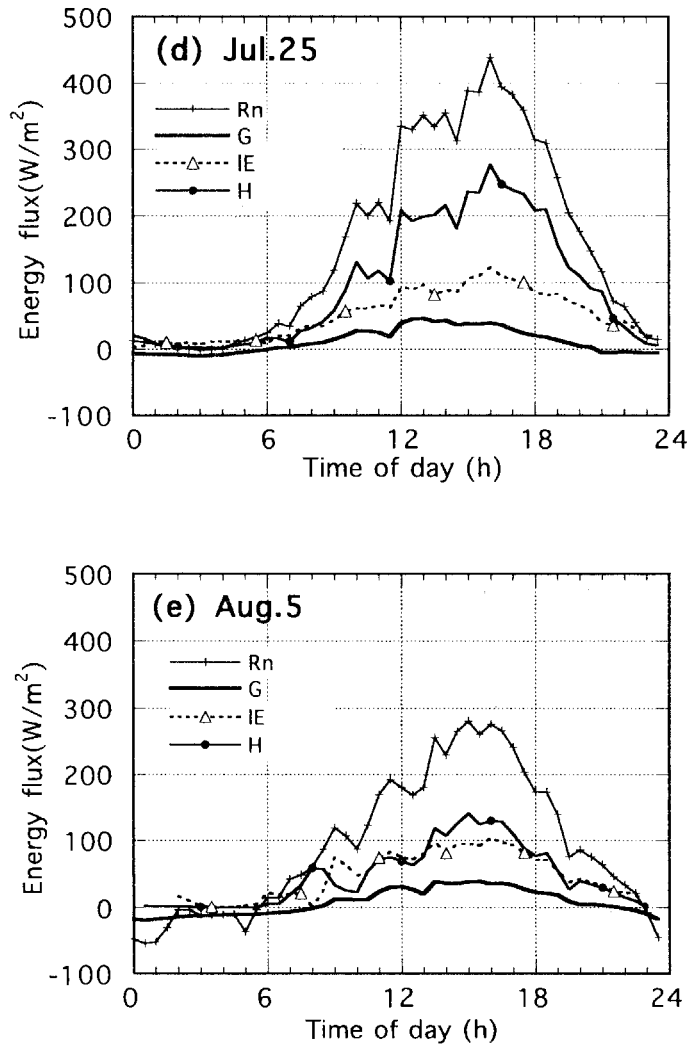

Fig. 6 Daily variations of the heat budget components for representative days (a: mid-June, b: late June, c: mid-July, d: late July, and e: early August) at the IBP site. R_n : net radiation flux, H : sensible heat flux, IE : latent heat flux, G : soil heat flux.

5.3 Intra-season variation of the micrometeorological characteristics over the tundra

Fig. 7 represents the seasonal trend of the daily summation of downward solar radiation R_{sd} net radiation R_n , and soil heat flux G . Fig. 8 represents the seasonal trends of daily average air temperature T_a and absolute humidity AH of the air (height 2.1 m), and Fig. 9 represents daily average wind speed of the highest level U_1 and wind direction (height 4.7 m) over the tundra. Daily average values were calculated using each 30 minute average.

The daily accumulation of solar radiation accounted for more than 25 MJ/m² per day on clear and relatively low wind speed days in the earlier half of measurement (from mid-June to mid-July) which was almost the same as that measured at the central part of Japan in summer. Net radiation ranged from 8 to 18 MJ/m² per day in late July, then decreased with solar radiation. Soil heat flux also changed with R_{sd} and/or R_n , but the amplitude of the fluctuation was smaller than those of R_{sd} and R_n . The long term trend of the contribution of G to R_n did not change remarkably those values ranging within 11–15 % of R_n . The share of R_n to R_{sd} was smaller in the earlier half period of the measurement compared to the latter half, because of the continuous solar radiation of the mid night sun. Solar energy mainly contributed to sensible heat by late July, but after August there was a few clear days and radiative cooling at night, thus the solar energy did not contribute to the sensible heat.

The amplitude of the daily average air temperature was large in mid summer, while the level of absolute humidity did not change remarkably. The maximum air temperature was observed in mid-July, which was almost three weeks after the peak of solar radiation. Higher air temperatures of more than 20°C were observed in the afternoon under both low wind speed and clear conditions, while, lower air temperatures of less than 0°C were observed on windy and foggy days.

Wind speed over the Arctic tundra was relatively high almost every day, and sometimes the daily average exceeded 10 m/s, of which the hourly average exceeded 15 m/s. These high wind speed might provide a large portion of sensible heat, especially in the measurement period before mid-July. Wind direction changed almost every day, and the dominant wind direction, which was different from the dominant direction reported by Herbert *et al* (1991), was northwest and east to southeast.

Fig. 7 Variations of daily fluxes of solar radiation, net radiation and soil heat over the Arctic dry tundra at the IBP site during the observation period.

IBP aveTrend615-825

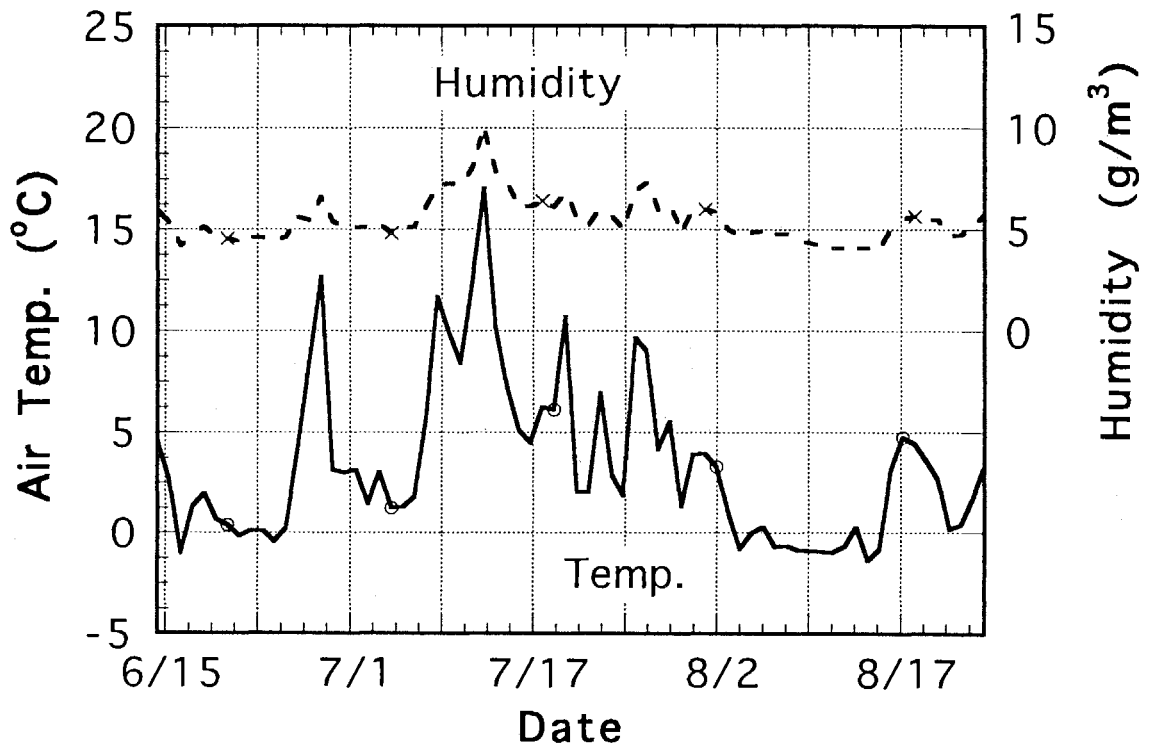

Fig. 8 Variations of daily mean temperature T_a , daily mean absolute humidity AH over the Arctic dry tundra of the IBP site.

Fig. 9 Variations of daily mean wind speed U_1 (4.7m in height) and wind direction at the IBP site.

6. Data tables

Data are listed as an every 30 minute average except for the background CO₂ concentration, B-CO₂. The dividing points of the averagings are 10 and 40 minutes, therefore the data with a time label of 00 were averaged between 41 minutes to 10 minutes of each hour. Only the background CO₂ concentrations listed with a time label of 00 were averaged from 01 to 60 minutes of each hour. The symbols are shown as follows:

Ta1	air temperature (°C) at the highest level of measurement
Ta2	air temperature (°C) at the middle level of measurement
Ta3	air temperature (°C) at the lowest level of measurement
AH1	absolute humidity (g/m ³) of the air at the highest level
AH2	absolute humidity (g/m ³) of the air at the middle level
AH3	absolute humidity (g/m ³) of the air at the lowest level
RH1	relative humidity (%) of the air at the highest level
RH2	relative humidity (%) of the air at the middle level
RH3	relative humidity (%) of the air at the lowest level
Ts1	soil temperature (°C) at 1 cm depth below the surface
Ts2	soil temperature (°C) at 5 cm depth below the surface
Ts3	soil temperature (°C) at 10 cm depth below the surface
Ts4	soil temperature (°C) at 20 cm depth below the surface
Rsd	solar radiation (W/m ²) (downward)
Rsu	reflection of solar radiation (W/m ²) (upward)
Rn	net radiation (W/m ²)
G	soil heat flux (W/m ²)
UVb	ultra violet radiation (W/m ²)
PAR	photosynthetic active radiation (μE/sm ²)
Albedo	Albedo = Rsu / Rsd
U1	wind speed (m/s) at the top measurement height
U3	wind speed (m/s) at the middle level
U5	wind speed (m/s) at the lowest measurement height

WD	wind direction (deg) specified from 0 to 360 degrees with clockwise rotation from north
z_0	roughness parameter (roughness length) (cm) over the tundra
u_*	friction velocity (m/s) over the tundra
Ri	Richardson number
Df	diffusion velocity (cm/s) over the tundra
CO ₂	CO ₂ concentration (ppm) over the tundra (at the same height of Ta1)
B-CO ₂	Background CO ₂ concentration (ppm) measured by CMDL/NOAA.

A mark shown in this column is represented in section 4.1.

7. Acknowledgments

This observational study was conducted as a collaboration between the Global Change Research Group of San Diego State University (SDSU) (Director, Prof. Walter C. Oechel) and the Division of Meteorology, National Institute of Agro-Environmental Sciences (NIAES). Budgetary support was provided by the Science and Technology Agency Japan (STA) and the San Diego State University Foundation. The Department of Wildlife Management, North Slope Borough (DWM/NSB), Barrow at Northern Arctic Research Laboratory (NARL) supported the observation by providing us with a laboratory, mechanic shop and accommodation facilities at the Arctic Research Facility (ARF). The authors acknowledge the persons of the above organizations, especially Mr. Benjamin P. Nageak, Director of the Department of Wildlife Management /NSB and Dr. George Craig of ARF/DWM/NBS. Regarding the background CO₂ data, we thank Dr. Daniel J. Endres of the Climatic Monitoring and Diagnostic Laboratory (CMDL), Barrow Station /NOAA, and Dr. Pieter Tans of CMDL, Boulder /NOAA for their efforts.

We also thank Mrs. Hiromi Matsubara, from the Lab. of micrometeorology, NIAES for her help with data processing, to Dr. Seisi Isobe, head of the meteorology division, NIAES and to Mr. Steven J. Hasting, Department of Biology/SDSU for their useful comments, to Dr. Susumu Sugihara and the staff of the International and Domestic Liaison division of NIAES, and to persons connected with the International Research Division, of the Agriculture, Forestry and Fisheries Research Council Secretariat, MAFF for their support for this observational study.

Symbols

Time	Alaska Standard Time (AKST) which is 8 hours later than GMT.
Ta1	air temperature ($^{\circ}\text{C}$) at the highest level of measurement
AH1	absolute humidity (g/m^3) of the air at the highest level
RH1	relative humidity (%) of the air at the highest level
Ta2	air temperature ($^{\circ}\text{C}$) at the middle level of measurement
AH2	absolute humidity (g/m^3) of the air at the middle level
RH2	relative humidity (%) of the air at the middle level
Ta3	air temperature ($^{\circ}\text{C}$) at the lowest level of measurement
AH3	absolute humidity (g/m^3) of the air at the lowest level
RH3	relative humidity (%) of the air at the highest level
Ts1	soil temperature ($^{\circ}\text{C}$) at 1 cm depth below the surface
Ts2	soil temperature ($^{\circ}\text{C}$) at 5 cm depth below the surface
Ts3	soil temperature ($^{\circ}\text{C}$) at 10 cm depth below the surface
Ts4	soil temperature ($^{\circ}\text{C}$) at 20 cm depth below the surface
Rsd	solar radiation (W/m^2) (downward)
Rsu	reflection of solar radiation (W/m^2) (upward)
Rn	net radiation (W/m^2)
G	soil heat flux (W/m^2)
UVb	ultra violet radiation (W/m^2)
PAR	photosynthetic active radiation ($\mu\text{E}/\text{sm}^2$)
Albedo	Albedo = $R_{\text{su}} / R_{\text{sd}}$
U1	wind speed (m/s) at the top measurement height
U3	wind speed (m/s) at the middle level
U5	wind speed (m/s) at the lowest measurement height
WD	wind direction (deg) specified from 0 to 360 degrees with clockwise rotation from north
z_0	roughness parameter (roughness length) (cm) over the tundra
u_*	friction velocity (m/s) over the tundra
Ri	Richardson number
Df	diffusion velocity (cm/s) over the tundra
CO2	CO ₂ concentration (ppm) over the tundra (at the same height of Ta1)
B-CO2	Background CO ₂ concentration (ppm) measured by CMDL/NOAA. A mark shown in this column is represented in section 4.1.
